Title:	Feature-testing recommendations for C++
Audience:	SG10, EWG, LEWG

Feature-testing recommendations for C++

[-1] Preface

- [1] At the July 2017 (Toronto) meeting, a poll was taken in EWG:
- Do we feel that the plenary should formally approve SD-6 revisions?
4 | 9 | 14 | 4 | 1
Ville: That's 13-5, so there's some feeling that it might be a good idea.
- [2] To pursue this idea, it would make sense for EWG and LEWG (for starters) to consider the content of this document, probably more closely than they have in the past.

1. [C++14 features](#)

2. [C++17 features](#)
6. [Annex: Model wording for a Technical Specification](#)
7. [Revision history](#)

[1] Introduction

- [1] At the September 2013 (Chicago) meeting of WG21, there was a five-way poll of all of the C++ experts in attendance – approximately 80 – concerning their support for the approach described herein for feature-testing in C++. The results of the poll:

Strongly favor	Favor	Neutral	Oppose	Strongly oppose
lots	lots	1	0	0

- [2] General support for these recommendations was reaffirmed at the 2015 October (Kona) meeting, as indicated by the following straw poll:

- [3] Should WG21 encourage, but not require, feature-test macros for proposals?

Strongly favor	Favor	Neutral	Against	Strongly against
50	13	7	3	2

- [4] This document was subsequently designated WG21's SD-6 (sixth standing document), which will continue to be maintained by SG10.

[2] Explanation and rationale for the approach

[2.1] Problem statement

- [1] The pace of innovation in the standardization of C++ makes long-term stability of implementations unlikely. Features are added to the language because programmers want to use those features. Features are added to (the working draft of) the standard as the features become well-specified. In many cases a feature is added to an implementation well before or well after the standard officially introducing it is approved.
- [2] This process makes it difficult for programmers who want to use a feature to know whether it is available in any given implementation. Implementations rarely leap from one formal revision of the standard directly to the next; the implementation process generally proceeds by smaller steps. As a result, testing for a specific revision of the standard (e.g. by examining the value of the `__cplusplus` macro) often gives the wrong answer.

Implementers generally don't want to appear to be claiming full conformance to a standard revision until all of its features are implemented. That leaves programmers with no portable way to determine which features are actually available to them.

[3] It is often possible for a program to determine, in a manner specific to a single implementation, what features are supported by that implementation; but the means are often poorly documented and ad hoc, and sometimes complex – especially when the availability of a feature is controlled by an invocation option. To make this determination for a variety of implementations in a single source base is complex and error-prone.

[2.2] Status quo

[1] Here is some code that attempts to determine whether rvalue references are available in the implementation in use:

```
#ifndef __USE_RVALUE_REFERENCES
    #if (__GNUC__ > 4 || __GNUC__ == 4 && __GNUC_MINOR__ >= 3) || \
        _MSC_VER >= 1600
        #if __EDG_VERSION__ > 0
            #define __USE_RVALUE_REFERENCES (__EDG_VERSION__ >= 410)
        #else
            #define __USE_RVALUE_REFERENCES 1
        #endif
    #elif __clang__
        #define __USE_RVALUE_REFERENCES __has_feature(cxx_rvalue_references)
    #else
        #define __USE_RVALUE_REFERENCES 0
    #endif
#endif
```

[2] First, the GNU and Microsoft version numbers are checked to see if they are high enough. But then a check is made of the EDG version number, since that front end also has compatibility modes for both those compilers, and defines macros indicating (claimed) compatibility with them. If the feature wasn't implemented in the indicated EDG version, it is assumed that the feature is not available – even though it is possible for a customer of EDG to implement a feature before EDG does.

[3] Fortunately Clang has ways to test specifically for the presence of specific features. But unfortunately, the function-call-like syntax used for such tests won't work with a standard preprocessor, so this fine new feature winds up adding its own flavor of complexity to the mix.

[4] Also note that this code is only the beginning of a real-world solution. A complete solution would need to take into account more compilers, and also command-line option settings specific to various compilers.

[2.3] Characteristics of the proposed solution

[1] To preserve implementers' freedom to add features in the order that makes the most sense for themselves and their customers, implementers should indicate the availability of each separate feature by adding a definition of a macro with the name corresponding to that feature.

[2] **Important note:** By recommending the use of these macros, WG21 is **not** making any feature optional; the absence of a definition for the relevant feature-test macro does not make an implementation that lacks a feature conform to a standard that requires the feature. However, if implementers and programmers follow these recommendations, portability of code between real-world implementations should be improved.

[3] To a first approximation, a feature is identified by the WG21 paper in which it is specified, and by which it is introduced into the working draft of the standard. Not every paper introduces a new feature worth a feature-test macro, but every paper that is not just a collection of issue resolutions is considered a candidate; exceptions are explicitly justified.

[4] For C++14, the feature-test macro name generally consists of some combination of words from the title of the paper. In the future, it is hoped that every paper will include its own recommendations concerning feature-test macro names.

[5] The value specified for a feature-test macro is based on the year and month in which the feature is voted into the working draft. In a case where a feature is subsequently changed in a significant way, but arguably remains the same feature, the value of the macro is changed to indicate the “revision level” of the specification of the feature. However, in most cases it is expected that the presence of a feature can be determined by the presence of any non-zero macro value; for example:

```
template<typename T>
struct use_empty_base_opt :
    std::integral_constant<bool,
        std::is_empty<T>::value
    >
{
    #if __cpp_lib_is_final
        && !std::is_final<T>::value
    #endif
    >
};
```

[6] To avoid the user's namespace, names of macros for language features are prefixed by “__cpp_”; for library features, by “__cpp_lib_”. A library feature that doesn't introduce a new header is expected to be defined by the header(s) that implement the feature.

[3] Recommendations

[3.1] Introduction

[1] For the sake of improved portability between partial implementations of various C++ standards, WG21 (the ISO technical committee for the C++ programming language) recommends that implementers and programmers follow the guidelines in this document concerning feature-test macros.

[2] Implementers who provide a new standard feature should define a macro with the recommended name and value, in the same circumstances under which the feature is available (for example, taking into account relevant command-line options), to indicate the presence of support for that feature.

[3] Programmers who wish to determine whether a feature is available in an implementation should base that determination on the state of the macro with the recommended name. (The absence of a tested feature may result in a program with decreased functionality, or the relevant functionality may be provided in a different way. A program that strictly depends on support for a feature can just try to use the feature unconditionally; presumably, on an implementation lacking necessary support, translation will fail. Therefore, if the most useful purpose for a feature-test macro would be to control the inclusion of a `#error` directive if the feature is unavailable, that is considered inadequate justification for the macro. Note that the usefulness of a test macro for a feature is completely independent of the usefulness of the feature itself.)

[3.2] Testing for the presence of a header: `__has_include`

[1] It is impossible for a C++ program to directly, reliably and portably determine whether or not a library header is available for inclusion. Conditionally including a header requires the use of a configuration macro, whose setting can be determined by a configuration-test process at build time (reliable, but less portable), or by some other means (often not reliable or portable).

[2] To solve this general problem, WG21 recommends that implementers provide, and programmers use, the `__has_include` feature.

[3.2.1] Syntax

h-preprocessing-token:
any *preprocessing-token* other than `>`

h-pp-tokens:
 h-preprocessing-token
 h-pp-tokens h-preprocessing-token

has-include-expression:
 `__has_include ( header-name )`
 `__has_include ( string-literal )`
 `__has_include ( < h-pp-tokens > )`

[3.2.2] Semantics

[1] In the first form of the *has-include-expression*, the parenthesized *header-name* token is not subject to macro expansion. The second and third forms are considered only if the first form does not match, and the preprocessing tokens are processed just as in normal text.

[2] A *has-include-expression* shall appear only in the controlling constant expression of a `#if` or `#elif` directive ([cpp.cond] 16.1). Prior to the evaluation of such an expression, the source file identified by the parenthesized preprocessing token sequence in each contained *has-include-expression* is searched for as if that preprocessing token sequence were the *pp-tokens* in a `#include` directive, except that no further macro expansion is performed. If such a directive would not satisfy the syntactic requirements of a `#include` directive, the program is ill-formed. The *has-include-expression* is replaced by the *pp-number* 1 if the search for the source file succeeds, and by the *pp-number* 0 if the search fails.

[3] The `#ifdef` and `#ifndef` directives, and the `defined` conditional inclusion operator, shall treat `__has_include` as if it were the name of a defined macro. The identifier `__has_include` shall not appear in any context not mentioned in this section.

[3.2.3] Example

[1] This demonstrates a way to use a library optional facility only if it is available.

```
#ifdef __has_include
#  if __has_include(<optional>)
#    include <optional>
#    define have_optional 1
#  elif __has_include(<experimental/optional>)
#    include <experimental/optional>
#    define have_optional 1
#    define experimental_optional
#  else
#    define have_optional 0
#  endif
#endif
```

[3.3] Testing for the presence of an attribute: `__has_cpp_attribute`

[1] A C++ program cannot directly, reliably, and portably determine whether or not a standard or vendor-specific attribute is available for use. Testing for attribute support generally requires complex macro logic, as illustrated above for language features in general.

[2] To solve this general problem, WG21 recommends that implementers provide, and programmers use, the `__has_cpp_attribute` feature.

[3.3.1] Syntax

has-attribute-expression:
 `__has_cpp_attribute ( attribute-token )`

[3.3.2] Semantics

[1] A *has-attribute-expression* shall appear only in the controlling constant expression of a `#if` or `#elif` directive ([cpp.cond] 16.1). The *has-attribute-expression* is replaced by a non-zero pp-number if the implementation supports an attribute with the specified name, and by the pp-number 0 otherwise.

[2] For a standard attribute, the value of the `__has_cpp_attribute` macro is based on the year and month in which the attribute was voted into the working draft. In the case where the attribute is vendor-specific, the value is implementation-defined. However, in most cases it is expected that the availability of an attribute can be detected by any non-zero result.

[3] The `#ifdef` and `#ifndef` directives, and the `defined` conditional inclusion operator, shall treat `__has_cpp_attribute` as if it were the name of a defined macro. The identifier `__has_cpp_attribute` shall not appear in any context not mentioned in this section.

[3.3.3] Example

[1] This demonstrates a way to use the attribute `[[deprecated]]` only if it is available.

```
#ifndef __has_cpp_attribute
# define __has_cpp_attribute(x) 0
#endif
#ifdef __has_cpp_attribute
#if __has_cpp_attribute(deprecated)
# define ATTR_DEPRECATED(msg) [[deprecated(msg)]]
#else
# define ATTR_DEPRECATED(msg)
#endif
#endif
```

[3.4] C++17 features

[1] The following table itemizes all the changes that were made to the working draft for C++17 as specified in a WG21 technical document. (Changes that were made as specified in a core or library issue are not generally included.)

[2] The table is sorted by the section of the standard primarily affected. The “Doc. No.” column links to the paper itself on the committee web site. The “Macro Name” column links to the relevant portion of the “Detailed explanation and rationale” annex of this document. When the recommendation is to change the value of a macro previously recommended to be defined, the “Value” column links to the table entry for the previous recommendation.

[3] For library features, the “Header” column identifies the header that is expected to define the macro, although the macro may also be predefined. For language features, the macro must be predefined.

Significant changes to C++17					
Doc. No.	Title	Primary Section	Macro Name	Value	Header
P0296R2	Forward progress guarantees: Base definitions	4.7	none		
P0299R1	Forward progress guarantees for the Parallelism TS features	4.7, 28.4	none		
N4086	Removing trigraphs??!	5	none

[3.5]
 C++14 features

- [1]
 The following table itemizes all the changes that were made to the working draft for C++14 as specified in a WG21 technical document. (Changes that were made as specified in a core or library issue are not generally included.)
- [2]
 The table is sorted by the section of the standard primarily affected. The “Doc. No.” column links to the paper itself on the committee web site. The “Macro Name” column links to the relevant portion of the “Detailed explanation and rationale” annex of this document. When the recommendation is to change the value of a macro previously recommended to be defined, the “Value” column links to the table entry for the previous recommendation.
- [3]
 For library features, the “Header“ column identifies the header that is expected to define the macro, although the macro may also be predefined. For language features, the macro must be predefined.

Significant changes to C++14

Doc. No.	Title	Primary Section	Macro Name	Value	Header

[3.7] **Conditionally-supported constructs**

[1] *STUB*

[3.8] C++98 features

[1] *STUB: especially for exception handling and RTTI*

[2] With very few exceptions, the features of C++98 have all been implemented in virtually every C++ compiler. But in many compilers, some of them can be enabled/disabled. It is recommended that the macros in the following table should be used to indicate whether one of these features is enabled in the current compilation.

Feature	Primary section	Macro name	Value	Header
Run-time type identification	5.2	<code>__cpp_rtti</code>	199711	<i>predefined</i>
Exception handling	15	<code>__cpp_exceptions</code>	199711	<i>predefined</i>

[3.9] Features published and later removed

[3.9.1] Features removed from C++17

Features in the CD of C++17, subsequently removed

Doc. No.	Title	Primary Section	Macro Name	Value	Header
P0077R2	<u>is callable, the missing INVOKE related trait</u>	20.15	__cpp_lib_is_callable	201603	<code><type_traits></code>
P0181R1	<u>Ordered By Default</u>	20.14 , 23.4 , 23.6	__cpp_lib_default_order	201606	<code><type_traits></code>
P0156R0	<u>Variadic lock_guard</u>	30.4	__cpp_lib_lock_guard_variadic	201510	<code><thread></code> <code><mutex></code>

[3.9.2] Features removed from C++14

Features in the first CD of C++14, subsequently removed to a Technical Specification

Doc. No.	Title	Primary Section	Macro Name	Value	Header
N3639	Runtime-sized arrays with automatic storage duration	8.3	__cpp_runtime_arrays	201304	<i>predefined</i>
N3672	A proposal to add a utility class to represent optional objects	20.5	__has_include(<optional>)	1	<i>predefined</i>
N3662	C++ Dynamic Arrays	23.2, 23.3	__has_include(<dynarray>)	1	<i>predefined</i>

[1] The intention is that an implementation which provides runtime-sized arrays as specified in the first CD should define `__cpp_runtime_arrays` as 201304. The expectation is that a later document specifying runtime-sized arrays will specify a different value for `__cpp_runtime_arrays`.

[A] Annex: Recommendations from Technical Specifications (informative)

[2] In this annex, feature-test macros from all WG21 Technical Specifications are collected, for convenience.

[A.10] C++ Extensions for Library Fundamentals

[1] The recommended macro name is `"__cpp_lib_experimental_"` followed by the string in the "Macro Name Suffix" column.

Doc. No.	Title	Primary Section	Macro Name Suffix	Value	Header
N3915	<code>apply()</code> call a function with arguments from a tuple	3.2.2	<code>apply</code>	201402	<code><experimental/tuple></code>
N3932	Variable Templates For Type Traits	3.3.1	<code>type_trait_variable_templates</code>	201402	<code><experimental/type_traits></code>
N3866	Invocation type traits	3.3.2	<code>invocation_type</code>	201406	<code><experimental/type_traits></code>
N3916	Type-erased allocator for <code>std::function</code>	4.2	<code>function_erased_allocator</code>	201406	<code><experimental/functional></code>
N3905	Extending <code>std::search</code> to use Additional Searching Algorithms	4.3	<code>boyer_moore_searching</code>	201411	<code><experimental/functional></code>
N3672, N3793	A utility class to represent optional objects	5	<code>optional</code>	201411	<code><experimental/optional></code>

N3804	Any Library Proposal	6	any	201411	<experimental/any>
N3921	string_view: a non-owning reference to a string	7	string_view	201411	<experimental/string_view>
N3920	Extending shared_ptr to Support Arrays	8.2	shared_ptr_arrays	201406	<experimental/memory>
N3916	Polymorphic Memory Resources	8.4	memory_resources	201402	<experimental/memory_resource>
N3916	Type-erased allocator for std::promise	9.2	promise_erased_allocator	201406	<experimental/future>
N3916	Type-erased allocator for std::packaged_task	9.3	packaged_task_erased_allocator	201406	<experimental/future>
N3925	A sample Proposal	10.3	sample	201402	<experimental/algorithm>

[A.11] C++ Extensions for Parallelism

Name	Value	Header
__cpp_lib_experimental_parallel_algorithm	201505	<experimental/algorithm> <experimental/exception_list> <experimental/execution_policy> <experimental/numeric>

[A.12] File System Technical Specification

Name	Value	Header
__cpp_lib_experimental_filesystem	201406	<experimental/filesystem>

[A.13] C++ Extensions for Transactional Memory

Name	Value	Header
__cpp_transactional_memory	201505	<i>predeclared</i>
<u>has_cpp_attribute(optimize_for_synchronized)</u>	<u>201505</u>	<u><i>predeclared</i></u>

[1] The Technical Specification for transactional memory specifies a new attribute, but does not specify a value for a *has-attribute-expression* for that attribute.

[B] Annex: Detailed explanation and rationale (informative)

[1] Many of the examples here have been shamelessly and almost brainlessly plagiarized from the cited paper. Assistance with improving examples is solicited.

[B.1] C++14 features

[B.1.1] N3323: A Proposal to Tweak Certain C++ Contextual Conversions

[1] This paper specifies a small change that is considered to be more of a bug fix than a new feature, so no macro is considered necessary.

[B.1.2] N3421: Making Operator Functors greater<>

[1] Example:

```
#if __cpp_lib_transparent_operators
    sort(v.begin(), v.end(), greater<>());
#else
    sort(v.begin(), v.end(), greater<valueType>());
#endif
```

[B.1.3] N3462: std::result_of and SFINAE

[1] The macro __cpp_lib_result_of_sfinae was originally erroneously recommended to be defined in the unrelated header <functional>. This error is being corrected, because it is believed that no implementation actually followed the erroneous recommendation.

[2] Example:

```
template<typename A>
#if __cpp_lib_result_of_sfinae
    typename std::result_of<inc(A)>::type
#else
    decltype(std::declval<inc>()(std::declval<A>()))
#endif
try_inc(A a);
```

[B.1.4] N3469: Constexpr Library Additions: chrono

N3470: Constexpr Library Additions: containers

N3471: Constexpr Library Additions: utilities

[1] These papers just add constexpr to the declarations of several dozen library functions in various headers. It is not clear that a macro to test for the presence of these changes would be sufficiently useful to be worthwhile.

[B.1.5] N3472: Binary Literals in the C++ Core Language

[1] Example:

```
int const packed_zero_to_three =
#if __cpp_binary_literals
    0b00011011;
#else
    0x1B;
#endif
```

[B.1.6] N3545: An Incremental Improvement to `integral_constant`

[1] Example:

```
constexpr bool arithmetic =
#if __cpp_lib_integral_constant_callable
    std::is_arithmetic<T>{}();
#else
    static_cast<bool>(std::is_arithmetic<T>{});
#endif
```

[B.1.7] N3624: Core Issue 1512: Pointer comparison vs qualification conversions

[1] This paper contained the wording changes to resolve a core issue. It did not introduce a new feature, so no macro is considered necessary.

[B.1.8] N3638: Return type deduction for normal functions

[1] This paper describes two separate features: the ability to deduce the return type of a function from the return statements contained in its body, and the ability to use `decltype(auto)`. These features can be implemented independently, so a macro is recommended for each.

[2] Examples:

```
template<typename T>
auto abs(T x)
#ifdef __cpp_return_type_deduction
    -> decltype(x < 0 ? -x : x)
#else
{
    return x < 0 ? -x : x;
}
```

[B.1.9] N3639: Runtime-sized arrays with automatic storage duration

[1] This was removed from C++14 to TS 19569.

[2] Example:

```
#if __cpp_runtime_arrays
    T local_buffer[n];           // more efficient than vector
#else
    std::vector<T> local_buffer(n);
#endif
```

[B.1.10] N3642: User-defined Literals for Standard Library Types

[1] This paper specifies user-defined literal operators for two different standard library types, which could be implemented independently. Furthermore, user-defined literal operators are expected to be added later for at least one other library type. So for consistency and flexibility, each type is given its own macro.

[2] Examples:

[B.1.11] N3644: Null Forward Iterators

[1] Example:

[B.1.12] N3648: Wording Changes for Generalized Lambda-capture

[1] Example:

[B.1.13] N3649: Generic (Polymorphic) Lambda Expressions

[1] Example:

[B.1.14] N3651: Variable Templates

[1] Example:

[B.1.15] N3652: Relaxing constraints on `constexpr` functions / `constexpr` member functions and `implicit const`

[1] The major change proposed by this paper is considered to be strictly a further development of the `constexpr` feature of C++11. Consequently, the

recommendation here is to give an increased value to the macro indicating C++11 support for constexpr.

[2] Example:

[B.1.16] N3653: Member initializers and aggregates

[1] Example:

[B.1.17] N3654: Quoted Strings Library Proposal

[1] Example:

[B.1.18] N3655: TransformationTraits Redux

[1] Example:

[B.1.19] N3656: make_unique

[1] Example:

[B.1.20] N3657: Adding heterogeneous comparison lookup to associative containers

[1] Example:

[B.1.21] N3658: Compile-time integer sequences

[1] Example:

[B.1.22] N3659: Shared locking in C++

[1] The original recommendation, of a macro defined in header <mutex>, was not useful, and has been retracted.

[2] For new headers, we have a long-term solution that uses __has_include. There was not sufficient support and a number of objections against adding macros to existing library header files, as there was not consensus on a place to put them.

[3] There is also a simple workaround for users that are not using libraries that define the header file: supplying their own header that is further down the search path than the library headers.

[4] Example:

```
#if __has_include(<shared_mutex>)
#include <shared_mutex>

// code that uses std::shared_mutex
#endif
```

[B.1.23] N3662: C++ Dynamic Arrays

[1] This was removed from C++14 to TS 19569.

[2] Example:

[B.1.24] N3664: Clarifying Memory Allocation

[1] The substantive change in this paper just relaxes a restriction on implementations. There is no new feature for a programmer to use, so no macro is considered necessary.

[B.1.25] N3667: Drafting for Core 1402

[1] This paper contained the wording changes to resolve a core issue. It did not introduce a new feature, so no macro is considered necessary.

[B.1.26] N3668: exchange() utility function

[1] Example:

[B.1.27] N3669: Fixing constexpr member functions without const

[1] This paper contained the wording changes to ensure that a minor change proposed by N3652 did not impact the standard library. It did not introduce a new feature, so no macro is considered necessary.

[B.1.28] N3670: Wording for Addressing Tuples by Type

[1] Example:

[B.1.29] N3671: Making non-modifying sequence operations more robust

[1] Example:

[B.1.30] N3672: A proposal to add a utility class to represent optional objects

- [1] This was removed from C++14 to TS 19568.
- [2] See [N3659](#) for rationale.
- [3] Example:

```
#if __has_include(<optional>)
#include <optional>

// code that uses std::optional
#endif
```

[B.1.31] N3673: C++ Library Working Group Ready Issues Bristol 2013

- [1] This paper was just a collection of library issues. It did not introduce a new feature, so no macro is considered necessary.

[B.1.32] N3760: ~~[[deprecated]] attribute~~

- [1] ~~Differentiating attribute availability based on compiler-specific macros is error-prone. Since vendors are allowed to provide implementation-specific attributes in addition to standards-based attributes, this feature provides a uniform, future-proof way to test the availability of attributes.~~
- [2] **Example:**

```
#ifndef __has_cpp_attribute
# if __has_cpp_attribute(deprecated)
# define ATTR_DEPRECATED(msg) [[deprecated(msg)]]
# else
# define ATTR_DEPRECATED(msg)
# endif
#endif

ATTR_DEPRECATED("f() has been deprecated") void f();
```

[B.1.33] N3776: Wording for ~future

- [1] The change made by this paper is a bug fix, and no macro is considered necessary.

[B.1.34] N3778: C++ Sized Deallocation

- [1] Example:

[B.1.35] N3779: User-defined Literals for std::complex

- [1] Example:

[B.1.36] N3781: Single-Quotation-Mark as a Digit Separator

- [1] Writing code that uses digit separators conditionally when they are available would require:
- either duplicating constants, presumably containing large numbers of digits, which would be error-prone and difficult to maintain,
 - or using a scheme based on macros and token concatenation, which would effectively take the place of digit separators as supported by the language.
- [2] Thus it is believed that a macro indicating support for digit separators in the language would not be sufficiently useful.

[B.1.37] N3786: Prohibiting "out of thin air" results in C++14

- [1] The change made by this paper is a bug fix, and no macro is considered necessary.

[B.1.38] N3789: Constexpr Library Additions: functional

- [1] See [N3471](#) for rationale.

[B.1.39] N3887: Consistent Metafunction Aliases

- [1] Example:

[B.1.40] N3891: A proposal to rename shared_mutex to shared_timed_mutex

- [1] Example:

[B.1.41] N3910: What can signal handlers do? (CWG 1441)

- [1] The change made by this paper is a bug fix, and no macro is considered necessary.

[B.1.42] N3924: Discouraging rand() in C++14

[1] The change made by this paper is not normative; no macro is necessary.

[B.1.43] N3927: Definition of Lock-Free

[1] The change made by this paper is a bug fix, and no macro is considered necessary.

[B.1.44] LWG issue 2112: User-defined classes that cannot be derived from

[1] Libraries that want to do empty-base optimization could reasonably want to use `!is_final && is_empty` if `is_final` exists, and fall back to just using `is_empty` otherwise.

[2] Example:

```
template<typename T>
struct use_empty_base_opt :
    std::integral_constant<bool,
        std::is_empty<T>::value
    >
{
    #if __cpp_lib_has_is_final
        && !std::is_final<T>::value
    #endif
};
```

[B.1.45] LWG issue 2247: Type traits and `std::nullptr_t`

[1] Example:

[B.1.46] LWG issue 2249: Remove `gets` from `<cstdio>`

[1] Since portable, well-written code does not use the `gets` function at all, there is no need for a macro to indicate whether it is available.

[B.1.47] LWG issue 2285: `make_reverse_iterator`

[1] Example:

[B.2] C++17 features

[B.2.1] N3911: TransformationTrait Alias `void_t`

[1] Example:

```
#if __cpp_lib_void_t
    using std::void_t;
#else
    template< class... > using void_t = void;
#endif
```

[B.2.2] N3922: New Rules for auto deduction from braced-init-list

[1] This change is considered a fix to a problem in C++14, not a new feature, so no macro is recommended. Code that needs to work both with and without this change should not attempt to deduce a type from a direct *braced-init-list* initializer.

[B.2.3] N3928: Extending `static_assert`

[1] Example:

```
#if __cpp_static_assert
#define Static_Assert(cond) static_assert(cond)
#else
#define Static_Assert(cond) static_assert(cond, #cond)
#endif
#define Static_Assert_Msg(cond, msg) static_assert(cond, msg)
#else
#define Static_Assert(cond)
#define Static_Assert_Msg(cond, msg)
#endif
```

[B.2.4] N4051: Allow `typename` in a template template parameter

[1] This is a minor stylistic extension; there is no difference in functionality or verbosity between code that uses the `class` keyword and code that uses the `typename` keyword in this context. If portability is needed between implementations having and lacking this feature, generally it would be easier to continue to write code using `class` than to write and maintain conditional compilation to use `typename` when available. So a macro for this feature would not seem to be justified.

[B.2.5] N4086: Removing trigraphs??!

[1] This is a very low-level change, purely lexical. Writing code to use trigraphs when they are available and different characters when trigraphs are not available would be tedious, and the resulting code would be even uglier than code that just uses trigraphs.

[2] Even in circumstances where use of a character not in the ISO/IEC 646 Basic Character Set is problematic, it would generally be easier to use

alternative tokens (a.k.a. “digraphs”) than to conditionally use trigraphs.

[B.2.6] N4089: Safe conversions in `unique_ptr<T[]>`

[1] This is considered a fix for a library issue, to remove an unnecessary restriction; no macro is considered necessary.

[B.2.7] N4169: A proposal to add `invoke` function template

[1] Example:

```
template<typename F>
auto deref_fn(F&& f)
{
    return [f](auto&&... args) {
        #if __cpp_lib_invoke
            return *std::invoke(f, std::forward<decltype(args)>(args)...);
        #else
            return *f(std::forward<decltype(args)>(args)...);
        #endif
    };
}
```

[2] In this example, member function pointers are supported only if `invoke` is available.

[B.2.8] N4190: Removing `auto_ptr`, `random_shuffle()`, And Old `<functional>` Stuff

[1] These library features are removed because superior alternatives to them were introduced in C++11. Because these alternatives are superior, there is little motivation to maintain code that uses one of these obsolescent features when available.

[B.2.9] N4230: Nested namespace definition

[1] This feature doesn't provide any new functionality; it just makes it somewhat easier to write code. For code that needs to be portable to an implementation that doesn't provide this feature, it would be easier just to avoid using the feature than it would be maintain the code to use it when available but not otherwise. Therefore, a macro to indicate the availability of this feature would not seem to be justified.

[B.2.10] N4258: Cleaning-up `noexcept` in the Library

[1] Example:

```
template <class T, class Allocator = std::allocator<T>>
class myContainer {
    typedef std::allocator_traits<Allocator> alloc_traits;
public:
    ...
    myContainer& operator=(myContainer&& x)
#ifdef __cpp_lib_allocator_traits_is_always_equal
    noexcept(alloc_traits::propagate_on_container_move_assignment::value ||
             alloc_traits::is_always_equal::value);
#else
    noexcept(alloc_traits::propagate_on_container_move_assignment::value);
#endif
    ...
};
```

[2] Without the trait, the code will be correct, but container move-assignment would have fewer exception guarantees, especially with pre-C++11 stateless allocators. An implementation of a mutating algorithm might choose to use copy-assignment instead of move-assignment if the `noexcept` clause evaluates to false, because the implementation is unable to determine whether the allocator always compares equal.

[B.2.11] N4259: Wording for `std::uncaught_exceptions`

[1] Example:

```
bool throw_may_terminate()
{
    ...
    #if __cpp_lib_uncaught_exceptions
        return std::uncaught_exceptions() > 0;
    #else
        return std::uncaught_exception();
    #endif
}
```

[B.2.12] N4261: Proposed resolution for Core Issue 330: Qualification conversions and pointers to arrays of pointers

[1] This paper fixes a core language issue; no new feature is introduced.

[B.2.13] N4262: Wording for Forwarding References

[1] The changes detailed in this paper are solely editorial. It does not introduce any new feature.

[B.2.14] N4266: Attributes for namespaces and enumerators

[1] Example:

```
enum {
    old_val
#ifdef __cpp_enumerator_attributes
        [[deprecated]]
#endif
    , new_val };
```

[B.2.15] N4267: Adding u8 character literals

[1] This feature gives guaranteed access to the Unicode encoding for a 7-bit ASCII character even in an implementation that uses a different character encoding. In an application that needs this functionality, it would probably be easier simply to hard-code the numeric values of the needed encodings. Thus a macro for this feature would seem to be of limited usefulness.

[B.2.16] N4268: Allow constant evaluation for all non-type template arguments

[1] Example:

```
int n = 0, m = 0;
int &r = n;
template<int &> struct X {};
#ifdef __cpp_nontype_template_args
    X<r> x;
#else
    std::conditional<&r == &n, X<n>, X<m>>::type x;
#endif
```

[B.2.17] N4277: TriviallyCopyable reference_wrapper

[1] This paper imposes a new requirement on implementations, which most implementations had already satisfied. A reliable indication of when this requirement was not satisfied would have been useful for programming; an indication that it is satisfied would not be so useful.

[B.2.18] N4279: Improved insertion interface for unique-key maps

[1] Example:

```
#if __cpp_lib_map_try_emplace
    m.insert_or_assign("foo", std::move(p));
#else
    m["foo"] = std::move(p);
#endif
```

[2] In this example, if `insert_or_assign` is not available, the type of `p` must be default-constructible.

[B.2.19] N4280: Non-member size() and more

[1] Example:

```
auto n =
#ifdef __cpp_lib_nonmember_container_access
    std::size(c);
#else
    c.size();
#endif
```

[2] In this example, an array type is supported for `c` only if the nonmember `size` function is available.

[B.2.20] N4284: Contiguous Iterators

[1] The changes detailed in this paper are solely editorial. It does not introduce any new feature.

[B.2.21] N4285: Cleanup for exception-specification and throw-expression

[1] The changes detailed in this paper are solely editorial. It does not introduce any new feature.

[B.2.22] N4295: Folding expressions

[1] Example:

```
#if __cpp_fold_expressions
template<typename... T>
    auto sum(T... args) { return (args + ...); }
#else
auto sum() { return 0; }
template<typename T>
    auto sum(T t) { return t; }
template<typename T, typename... Ts>
    auto sum(T t, Ts... ts) { return t + sum(ts...); }
#endif
```

[B.2.23] N4366: LWG 2228 missing SFINAE rule

[1] This change fixes a defect in the library. No new feature is added, so no feature-test macro is needed.

[B.2.24] N4387: Improving pair and tuple

[1] This paper resolves some library issues. There is no new feature; no macro is required.

[B.2.25] N4389: Wording for bool_constant

[1] Example:

```
#if __cpp_lib_bool_constant
    template <bool B>
        using my_bool_constant = std::bool_constant<B>;
#else
    template <bool B>
        using my_bool_constant = std::integral_constant<bool, B>;
#endif
```

[B.2.26] N4508: A proposal to add shared_mutex (untimed)

[1] Example:

[2] Lenexa

[B.2.27] N4510: Minimal incomplete type support for standard containers

[1] Example:

[2] Lenexa

[B.2.28] P0001R1: Remove Deprecated Use of the register Keyword

[1] The simplest way to write code to be portable between implementations that have and lack this change is to avoid using the register keyword. A feature-test macro would not be sufficiently useful.

[B.2.29] P0002R1: Remove Deprecated operator++(bool)

[1] The simplest way to write code to be portable between implementations that have and lack this change is to avoid applying ++ to bool objects. A feature-test macro would not be sufficiently useful.

[B.2.30] P0004R1: Remove Deprecated iostreams aliases

[1] The simplest way to write code to be portable between implementations that have and lack this change is not to use the previously deprecated features. A feature-test macro would not be sufficiently useful.

[B.2.31] P0006R0: Adopt Type Traits Variable Templates from Library Fundamentals TS for C++17

[1] Example:

[2] Kona

[B.2.32] P0007R1: Constant View: A proposal for a std::as_const helper function template

[1] Example:

[2] Kona

[B.2.33] P0012R1: Make exception specifications be part of the type system

[1] Example:

[2] Kona

[B.2.34] P0013R1: Logical Operator Type Traits

[1] Example:

```
template<typename... T>
    using condition =
    #if __cpp_lib_logical_traits
        conjunction<is_pointer<decay_t<T>>...>;
    #else
        bool_constant<(is_pointer<decay_t<T>>::value && ...) >;
    #endif

template<typename... T>
    enable_if_t<condition<T...>::value>
    foo(T&&...) { }

template<typename... T>
    enable_if_t<!condition<T...>::value>
    foo(T&&...) { }
```

[2] Using conjunction is more efficient at compile-time, because it short-circuits and doesn't evaluate every expression in the pack expansion if it doesn't need to.

[B.2.35] P0061R1: __has_include for C++17

[1] The presence of this feature can be determined by testing whether the `__has_include` macro is defined. However, because it is a function-like macro, it has no specific value that can be tested.

[B.2.36] P0074R0: Making `std::owner_less` more flexible

[1] Example:

```
#if __cpp_lib_transparent_operators >= 201510
using generic_owner_less = std::owner_less<>;
#else
struct generic_owner_less {
    template<typename T, typename U>
    bool
    operator()(const std::shared_ptr<T>& p1,
               const std::shared_ptr<U>& p2) const
    { return p1.owner_before(p2); }
};
#endif
```

[B.2.37] P0092R1: Polishing `<chrono>`

[1] Example:

[2] Kona

[B.2.38] P0134R0: Introducing a name for brace-or-equal-initializers for non-static data members

[1] This change is entirely editorial; no feature is added, and no test macro is needed.

[B.2.39] P0136R1: Rewording inheriting constructors (core issue 1941 et al)

[1] This change is considered a minor tweak to the inheriting constructors feature, and mostly just fixes issues with the original description. However, it can change the behavior of some code. Therefore the value of the `__cpp_inheriting_constructors` macro is adjusted.

[2] Example:

[3] Kona

[B.2.40] P0156R0: Variadic `lock_guard`

[1] In a previous revision, it was recommended that a test macro for this feature be defined in `<thread>`. That was a mistake; the relevant code is actually in `<mutex>`.

[2] This feature was subsequently removed from C++17. The functionality it had provided is now provided by a `scoped_lock`.

[B.2.41] P0005R4: Adopt not `fn` from Library Fundamentals 2 for C++17

[1] Example:

[2] Jacksonville

[B.2.42] P0017R1: Extension to aggregate initialization

[1] Example:

[2] Jacksonville

[B.2.43] P0018R3: Lambda Capture of `*this` by Value as `[=,*this]`

[1] Example:

[2] Jacksonville

[B.2.44] P0024R2: The Parallelism TS Should be Standardized

[1] Example:

[2] Jacksonville

[B.2.45] P0025R0: An algorithm to "clamp" a value between a pair of boundary values

[1] Example:

[2] Jacksonville

[B.2.46] P0030R1: Proposal to Introduce a 3-Argument Overload to std::hypot

[1] Example:

[2] Jacksonville

[B.2.47] P0031R0: A Proposal to Add constexpr Modifiers to reverse_iterator, move_iterator, array and Range Access

[1] Jacksonville

[2] Example:

[B.2.48] P0033R1: Re-enabling shared from this

[1] Example:

```
template<class ObjectType>
void register_observers(ObjectType& obj)
{
    #if __cpp_lib_enable_shared_from_this
        auto wptr = obj.weak_from_this();
    #else
        auto sptr = obj.shared_from_this();
        // Fails if sptr is not std::shared_ptr
        // (e.g. std::experimental::shared_ptr or boost::shared_ptr)
        auto wptr = weak_ptr<decltype(sptr)::element_type>(sptr);
        sptr.reset(); // drop the strong reference as soon as possible
    #endif
    register_observer_1(wptr);
    register_observer_2(wptr);
}
```

[B.2.49] P0036R0: Unary Folds and Empty Parameter Packs

[1] This is a change to the original definition of the “unary fold” feature. The presence or absence of this change should be distinguished by the value of the __cpp_fold_expression macro.

[B.2.50] P0077R2: is_callable, the missing INVOKE related trait

[1] Example:

[2] Jacksonville

[B.2.51] P0138R2: Construction Rules for enum class Values

[1] This doesn't provide any new functionality; it just makes some kinds of code simpler to write. Code that needs to be portable to implementations lacking this feature would be still more complicated if it tried to use the new feature when available. So a macro for this feature would not seem to be justified.

[B.2.52] P0152R1: constexpr atomic<T>::is always lock free

[1] Example:

[2] Jacksonville

[B.2.53] P0154R1: constexpr std::hardware {constructive,destructive} interference_size

[1] Example:

[2] Jacksonville

[B.2.54] P0170R1: Wording for constexpr Lambda

[1] The changes proposed in this paper are considered to be an extension of the capabilities of the constexpr keyword. Therefore the presence or absence of this feature should be distinguished by the value of the __cpp_constexpr macro.

[B.2.55] P0184R0: Generalizing the Range-Based For Loop

[1] This is considered an extension of the range-based for statement. Therefore the presence or absence of this feature should be distinguished by the value of the __cpp_range_based_for macro.

[B.2.56] P0185R1: Adding [nothrow-]swappable traits

[1] Example:

```
template<class T>
void my_swap(T& x, T& y)
#if __cpp_lib_is_swappable
    noexcept(std::is_swappable_v<T>); // Covers all lvalue Swappable cases
#else
```

```
__noexcept(  
    std::is_nothrow_move_constructible_v<T> &&  
    std::is_nothrow_move_assignable_v<T>  
);  
#endif
```

[B.2.57] **P0218R1: Adopt the File System TS for C++17**

[1] Example:

[2] Jacksonville

[B.2.58] **P0220R1: Adopt Library Fundamentals V1 TS Components for C++17**

[B.2.59] **P0226R1: Mathematical Special Functions for C++17**

[1] Example:

[2] Jacksonville

[B.2.60] **P0245R1: Hexadecimal floating literals for C++**

[1] Example:

[2] Jacksonville

[B.2.61] **P0253R1: Fixing a design mistake in the searchers interface in Library Fundamentals**

[1] This is a fix that is applied to the searchers interface at the same time that it is incorporated into the standard. The unfixed state exists only in the TS, which has its own macro name and value. The new macro for the searchers interface in the standard, with its new value, will be enough to indicate that this fix is applied.

[B.2.62] **P0272R1: Give 'std::string' a non-const '.data()' member function**

[1] This doesn't provide any new functionality; it just makes some kinds of code simpler to write. Code that needs to be portable to implementations lacking this feature would be still more complicated if it tried to use the new feature when available. So a macro for this feature would not seem to be justified.

[B.2.63] **LWG2296: std::addressof should be constexpr**

[1] Example:

```
struct optional {  
    bool b;  
    T t;  
    constexpr T *get() {  
        return b ?  
#if __cpp_lib_addressof_constexpr  
        std::addressof(t)  
#else  
        &t  
#endif  
        : nullptr;  
    }  
};
```

[2] It is more important for get to be constexpr than for it to work if there is an overloaded operator&, so addressof is used only if it would actually work in a constant expression.

[3] Oulu:

[B.2.64] **P0028R4: Using attribute namespaces without repetition**

[1] This feature doesn't provide any new functionality; it just makes it somewhat easier to write code. For code that needs to be portable to an implementation that doesn't provide this feature, it would be easier just to avoid using the feature than it would be maintain the code to use it when available but not otherwise. Therefore, a macro to indicate the availability of this feature would not seem to be justified.

[B.2.65] **P0032R3: Homogeneous interface for variant, any and optional**

[B.2.66] **P0035R4: Dynamic memory allocation for over-aligned data**

[1] Example:

[B.2.67] **P0040R3: Extending memory management tools**

[B.2.68] **P0063R3: C++17 should refer to C11 instead of C99**

[1] This paper is primarily editorial. There are a few additional C library functions that are formally required as a result of these changes, but in many cases they are not under the control of the C++ library implementer. It might be possible to tell the difference by the value of the __STDC__ macro.

It's not clear that any real purpose would be served by recommending a C++-specific macro to distinguish the difference.

[B.2.69] P0083R3: Splicing Maps and Sets

[1] Example:

```
void update(std::set<X>& set, const X& elem, int val)
{
    auto pos = set.find(elem);
    if (pos == set.end())
        return;
    #if __cpp_lib_node_extract
        auto next = std::next(pos);
        auto x = set.extract(pos);
        x.value().update(val);
        set.insert(next, std::move(x));
    #else
        X tmp = *pos;
        pos = set.erase(pos);
        tmp.update(val);
        set.insert(pos, std::move(tmp));
    #endif
}
```

[2] The version using `extract` doesn't need to copy or move any `x` objects and performs no memory allocation.

[B.2.70] P0084R2: Emplace Return Type

[1] Code that needs to be portable between implementations with and without changes required by this paper should simply assume the previous rules.

[B.2.71] P0088R3: Variant: a type-safe union for C++17

[B.2.72] P0091R3: Template argument deduction for class templates

[B.2.73] P0127R2: Declaring non-type template parameters with `auto`

[1] Example:

[B.2.74] P0135R1: Wording for guaranteed copy elision through simplified value categories

[1] Example:

```
class NoCopyNoMove {
public:
    NoCopyNoMove(const NoCopyNoMove&) = delete;
    NoCopyNoMove &operator=(const NoCopyNoMove&) = delete;
    NoCopyNoMove(int a, int b, int c);
};

NoCopyNoMove factory(int a) {
    return {a, 2, 3}; // constructs return value in place
}

#ifdef __cpp_guaranteed_copy_elision
NoCopyNoMove indirectFactory(int a) {
    return factory(a); // ill-formed prior to C++17
}
#endif
```

[2] A library can provide the `indirectFactory` function depending on whether the implementation provides guaranteed copy elision. Code that uses the library should use the `factory` function if it needs to be portable to an implementation that doesn't provide guaranteed copy elision. Code that doesn't need such portability can just use the `indirectFactory` function.

[B.2.75] P0137R1: Core Issue 1776: Replacement of class objects containing reference members

[1] Example:

[B.2.76] P0145R3: Refining Expression Evaluation Order for Idiomatic C++

[1] Code that needs to be portable between implementations with and without changes required by this paper should simply assume the previous rules.

[B.2.77] P0163R0: shared_ptr::weak_type

[1] Example:

```
template<class ObjectType>
void register_observers(ObjectType& obj)
{
    auto sptr = obj.shared_from_this();
    #if __cpp_lib_shared_ptr_weak_type
        decltype(sptr)::weak_type wptr(sptr);
    #else
```

```
// Fails if sptr is not std::shared_ptr
// (e.g. std::experimental::shared_ptr or boost::shared_ptr)
auto wptr = weak_ptr<decltype(sptr)::element_type>(sptr);
#endif
    sptr.reset(); // drop the strong reference as soon as possible
    register_observer_1(wptr);
    register_observer_2(wptr);
}
```

[B.2.78] **P0174R2: Deprecating Vestigial Library Parts in C++17**

[1] This paper deprecates some library facilities for which superior alternatives exist. Code that needs to be portable should use the alternatives; a macro to enable code to adapt would not be useful.

[B.2.79] **P0175R1: Synopses for the C library**

[1] The changes proposed in this paper are entirely editorial; no macro is required.

[B.2.80] **P0180R2: Reserve a New Library Namespace Future Standardization**

[1] This paper does not describe a new feature. It describes a retracted feature: the ability of a program to define a namespace with any of a certain set of names. Portable code should avoid defining such a namespace; no macro is necessary.

[B.2.81] **P0181R1: Ordered By Default**

[1] Example:

[B.2.82] **P0209R2: make_from_tuple: apply for construction**

[1] Example:

[B.2.83] **P0217R3: Proposed wording for structured bindings**

[1] Example:

[B.2.84] **P0219R1: Relative Paths for Filesystem**

[B.2.85] **P0254R2: Integrating std::string_view and std::string**

[B.2.86] **P0258R2: has_unique_object representations - wording**

[1] Example:

[B.2.87] **P0283R2: Standard and non-standard attributes**

[1] This paper changed a global policy. It didn't introduce a new feature, so no macro is necessary.

[B.2.88] **P0292R2: constexpr if: A slightly different syntax**

[1] Example:

[B.2.89] **P0295R0: Adopt Selected Library Fundamentals V2 Components for C++17**

[1] Example:

[B.2.90] **P0296R2: Forward progress guarantees: Base definitions**
P0299R1: Forward progress guarantees for the Parallelism TS features

[1] These papers effectively add only definitions. The added guarantees are intended only to formalize widespread existing practice.

[B.2.91] **P0302R1: Removing Allocator Support in std::function**

[1] Since these constructors could not be used portably or reliably, there is no need for a feature test macro to indicate their absence.

[B.2.92] **P0305R1: Selection statements with initializer**

[1] This feature doesn't provide any new functionality; it just makes it somewhat easier to write code. For code that needs to be portable to an implementation that doesn't provide this feature, it would be easier just to avoid using the feature than it would be maintain the code to use it when available but not otherwise. Therefore, a macro to indicate the availability of this feature would not seem to be justified.

[B.2.93] **P0307R2: Making Optional Greater Equal Again**

[B.2.94] **P0336R1: Better Names for Parallel Execution Policies in C++17**

[1] It is believed that no implementation ever shipped using the previous names, so a macro for this would not be useful for real-world code.

[B.2.95] P0337R0: Delete operator= for polymorphic allocator

[1] This paper just fixes a defect. It doesn't add any new feature, so no macro is needed.

[B.2.96] P0346R1: A <random> Nomenclature Tweak

[1] The paper changes nothing but terminology, and is entirely editorial; no macro is needed.

[B.2.97] P0358R1: Fixes for not_fn

[1] The changes in this paper were adopted into the working draft of the standard at the same time as the not_fn feature they modify. The specification in the technical specification never appeared as such in any working draft of the standard, so a macro to distinguish the presence or absence of these changes is not considered necessary.

[B.2.98] P0371R1: Temporarily discourage memory_order_consume

[1] This paper is entirely editorial; no macro is required.

[B.2.99] P0386R2: Inline Variables

[1] Example:

[2] There are existing implementations that effectively provide inline variable semantics (i.e. make a weak definition) for an initialized variable. This example would be portable between such implementations, but not to an implementation for which an initialized variable creates a strong definition.

```
#if __cpp_inline_variables >= 201703
#define INLINE_VAR_DECL inline
#else
#define INLINE_VAR_DECL /*fingers crossed*/
#endif
```

```
INLINE_VAR_DECL constexpr piecewise_construct_t piecewise_construct{};
```

[B.2.100] P0391R0: Introducing the term "templated entity"

[1] This paper is entirely editorial, introducing a new term to make it easier to correctly draft the standard; no macro is necessary.

[B.2.101] P0392R0: Adapting string_view by filesystem paths

[B.2.102] P0393R3: Making Variant Greater Equal

[1] The changes in this paper were adopted into the working draft of the standard at the same time as the variant feature they modify. The specification in P0083R3 never appeared as such in any working draft, so a macro to distinguish the presence or absence of these changes is not considered necessary.

[B.2.103] P0394R4: Hotel Parallelifornia: terminate() for Parallel Algorithms Exception Handling

[1] This is considered to be a bug fix; no macro is necessary.

[B.2.104] P0398R0: Core issue 1518: Explicit default constructors and copy-list-initialization

[1] This paper describes a bug fix, not a new feature; no new macro is needed.

[2] Issaquah:

[B.2.105] P0003R5: Removing Deprecated Exception Specifications from C++17

[1] In general, a feature test macro is not needed for a deleted feature; portable code simply should not use the feature, unconditionally.

[B.2.106] P0067R5: Elementary string conversions

[B.2.107] P0195R2: Pack expansions in using-declarations

```
#if __cpp_variadic_using >= 201611
template<typename ...T> struct Callable : T... {
    using T::operator() ...;
};
#else
template<typename ...T> struct Callable;
template<typename T, typename ...U> struct Callable<T, U...> : T,
Callable<U...> {
    using T::operator();
    using Callable<U...>::operator();
};
template<typename T> struct Callable<T> : T {
    using T::operator();
};
template<> struct Callable<> {};
```

#endif

[B.2.108] P0497R0: Fixes to shared ptr support for arrays

[B.2.109] P0505R0: Wording for GB 50

[B.2.110] P0512R0: Class Template Argument Deduction Assorted NB resolution and issues

[B.2.111] P0522R0: Matching of template template-arguments excludes compatible templates

[1] Kona:

[B.2.112] P0156R2: Variadic lock_guard

[B.2.113] P0298R3: A byte type definition

[B.2.114] P0317R1: Directory Entry Caching for Filesystem

[B.2.115] P0604R0: Resolving GB 55, US 84, US 85, US 86

[1] Example:

```
#if __cpp_lib_is_invocable >= 201703
using std::is_invocable;
#elif __cpp_lib_void_t >= 201411
template<typename R, typename = void>
struct is_invocable_impl : std::false_type
{ };
template<typename R>
struct is_invocable_impl<R, std::void_t<typename R::type>> : std::true_type
{ };
template<typename F, typename... Args>
struct is_invocable : is_invocable_impl<std::result_of<F&&(Args&&...)>>::type
{ };
#else
#error either is_invocable or void_t is needed
#endif
```

[B.2.116] P0618R0: Deprecating <codecvt>

[1] There is no technical change associated with this paper, so a macro would not be useful.

[B.2.117] LWG2911: An is aggregate type trait is needed

```
#include <vector>
template<typename T, typename... Args>
T make(Args&&... args)
{
    #if __cpp_lib_is_aggregate
        if constexpr (std::is_aggregate_v<T>)
            return { std::forward<Args>(args)... };
        else
            #endif
            return T(std::forward<Args>(args)...);
}
struct Agg { int i; };
int main()
{
    auto v = make<std::vector<int>>(1, 2);
    #if __cpp_lib_is_aggregate
        // make<> only supports aggregates if std::is_aggregate is available
        auto a = make<Agg>(1);
    #endif
}
```

[C] Annex: Model wording for a Technical Specification

[1] It is recommended that Technical Specifications include the wording below. *yyyymm* indicates the year and month of the date of the TS.

[2] 1.x Feature testing [intro.features]

[3] An implementation that provides support for this Technical Specification shall define the feature test macro(s) in Table X.

Table X — Feature Test Macro(s)

Name	Value	Header
<code>__cpp_name</code>	<i>yyyymm</i>	<i>“predefined” OR “<name>”</i>

[D] Revision history

Date	Document	Description

2017-10-09	P0096R5	Recommendations from TS'es, and rationale, designated as informative annexes Resolved many questions about C++17 features
2017-07-26	P0096R4	Added C++17 features from Oulu, Issaquah and Kona
2016-03-08	SD-6 P0096R3	Updated from P0096R2
2016-02-23	P0096R2	Fixed recommendation for P0074R0 A few editorial fixes
2016-01-19	P0096R1	Added C++17 features from Kona
2015-09-16	P0096R0	Added C++17 features from Lenexa A few adjustments to C++17 recommendations Added model wording for a Technical Specification Added summaries of recommendations from TS'es
2015-04-09	N4440	Added C++17 features from Urbana A couple of changes to C++14 recommendations A few new C++11 features
2014-12-29	SD-6	Updated from N4200
2014-10-08	N4200	Updated for final C++14 Added more support for C++11 and C++98
2014-05-22	N4030	Updated for changes from Chicago and Issaquah meetings Added <code>__has_cpp_attribute</code> test
2013-11-27	SD-6	Initial publication No substantive changes from N3745
2013-08-28	N3745	Endorsed by WG21 membership
2013-06-27	N3694	Initial draft
