An idea or two on renaming the `nontype` tag

- An idea or two on renaming the `nontype` tag
 - Background
 - Discussion
 - References

Background

C++26 editorially^[1] removed the terminology "non-type template parameter" while adopting P2841^[2]. P3740R1^[3] followed up and discussed a few options to accommodate, including renaming the `std::nontype` tag to `std::constant_arg`.

Discussion

The name "nontype" was chosen not because it carries a non-type template argument, but because this name carries no meaning. `f` is a non-type template argument, so `nontype<f>` is calling your dog dog.

To convey some actual meaning, I suggest `witness`, drawn from the term "witness table."^[4]

A term serving a similar role, and one that more C++ users recognize, is `override`. However, the committee might want to reserve `std::override` for more valuable purposes.
